

How We deal with inheritance processes?

- **Table-per-hierarchy and discriminator configuration**
 - By default, EF maps the inheritance using the *table-per-hierarchy* (TPH) pattern. TPH uses a single table to store the data for all types in the hierarchy, and a discriminator column is used to identify which type each row represents
- **Table-per-type configuration**
 - in the TPT mapping pattern, all the types are mapped to individual tables. Properties that belong solely to a base type or derived type are stored in a table that maps to that type. Tables that map to derived types also store a foreign key that joins the derived table with the base table
- **Table-per-concrete-type configuration**
 - In the TPC mapping pattern, all the types are mapped to individual tables. Each table contains columns for all properties on the corresponding entity type. This addresses some common performance issues with the TPT strategy

Sequences

- **Basic usage**
 - use it to generate values for properties:
